Imagine a future where plastic is sustainable, green, biodegradable and manufactured without chemistry. A team of researchers is hoping to achieve exactly this by means of a ‘green soup’ of microalgae.

The idea is to extract oil from the algae and subject the fatty acids in the oil to the right enzymes. This way the researchers can transform the lipids into polymers. Polymers that are sustainable, manufactured using green biotechnology, without chemistry, and that are biodegradable and harmless to the environment. Polymers that, in principle, can be used to create any kind of plastic.

“They basically resemble LEGO® blocks that originate from microalgae. The blocks can be assembled to create any design. These are harmless and only contain biological molecules. That’s what we hope to develop,” says Associate Professor Peter Kristensen.

Improving nature by natural evolution

The process requires protein engineering. To convert the lipids extracted from microalgae into polymers, the lipids need to be chemically modified. This can be done by enzymes, but the enzymes that exist are not optimal for the process. Instead, the researchers engineer the right enzymes for the job via natural mutation - al evolution. This is where Charles Darwin is unleashed.

“Nature has already created enzymes that can do the job but not very efficiently. We’ll improve the enzymes so we can use their green properties in industry,” says Associate Professor Zheng Guo, whose colleague Associate Professor Peter Kristensen elaborates:

“Most chemicals today are made from petroleum, but that won’t be around forever and it isn’t sustainable. We need technology that doesn’t harm the environment,” says Associate Professor Zheng Guo.

“Creating a library of enzymes

“Enzymes are proteins in the biological system. Each and every one is created from the information stored in the DNA of the system. You can say that the DNA is the recipe for the enzymes, so we change a bit of text here and there to create an entire library of different enzymes. Then we look at the entire pool of mutated enzymes and choose the best one for the task through selection,” says Associate Professor Kristensen.

Nature has evolved this way since the dawn of time. Because of mutations and natural selection, life is able to survive in the most incredible places on earth: at the bottom of the ocean where no light ever reaches, to the highest peak of the Himalayas, and the coldest tip of the Antarctic.

From lipids to bio-polymers

Researchers at Aarhus University, in collaboration with colleagues at the Technical University of Denmark, the University of Cambridge and Kyoto University, have now come up with a possible solution – polymers produced from microalgae.

“Enzymes are proteins in the biological system. Each and every one is created from the information stored in the DNA of the system. You can say that the DNA is the recipe for the enzymes, so we change a bit of text here and there to create an entire library of different enzymes. Then we look at the entire pool of mutated enzymes and choose the best one for the task through selection,” says Associate Professor Kristensen.

Nature has evolved this way since the dawn of time. Because of mutations and natural selection, life is able to survive in the most incredible places on earth: at the bottom of the ocean where no light ever reaches, to the highest peak of the Himalayas, and the coldest tip of the Antarctic.
